Project Title:

Biochemical and structural studies of anticoagulant molecules

Level:

Master Student

Project Summary:

We study the properties of natural (from blood-feeding organisms) and engineered peptide anticoagulants, mostly targeting thrombin. For this, we characterize their properties in vitro and ex vivo, with the ultimate aim of understanding their molecular mechanism of action and the regulation of their physiological activity.

Work to be developed by the student:

Protein expression and purification; Macromolecular crystallization; Biochemical (activity assays; kinetic characterization) and biophysical (measurement of binding properties; structural determination) characterization.
